\* Short-Circuit protection is functioning only at the lower arms. Please select the value of the external shunt resistor such that the SC trip level is less than 34A.

\*\*Fault signal is asserted when the lower arm short circuit or control supply under-voltage protective functions operate. The fault output pulse-width  $t_{FO}$  depends on the capacitance value of  $C_{FO}$  according to the following approximate equation:  $C_{FO} = (12.2 \times 10^{-6}) \times t_{FO}$  {F} .

## Notes:

- To prevent input signal oscillations minimize wiring length to controller (~2cm). Additional RC filtering (C5 etc.) may be required. If filtering is added be careful to maintain proper dead time. See application notes for details.
  - Internal HVIC provides high voltage level shifting allowing direct connection of all six driving signals to the controller.
  - $F_O$  output is an open collector type. Pull up resistor (R3) should be adjusted to current sink capability of the module.
  - C4 sets the fault output duration and lock-out time.  $C4 @12.2E^{-6}$  x  $F_O$  22nF gives ~1.8ms
  - Boot strap supply component values must be adjusted depending on the PWM frequency and technique.
  - Wiring length associated with  $R_{SHUNT}$ ,  $RSF$ ,  $C_SF$  must be minimized to avoid improper operation of the SC function.
  - $RSF$ ,  $C_SF$  set short-circuit protection trip time. Recommend time constant is 1.5us-2.0us. See application notes.
  - Local decoupling/high frequency filter capacitors must be connected as close as possible to the modules pins.
  - The length of the DC link wiring between C6, C7, the DIP's P terminal and the shunt must be minimized to prevent excessive transient voltages. In particular C7 should be mounted as close to the DIP as possible.
  - Use high quality, tight tolerance current sensing resistor. Connect resistor as close as possible to the DIP's N terminal. Be careful to check for proper power rating. See application notes for calculation of resistance value.
